Information

- The test is closed-book.

- This test has *four* questions, totalling 20 marks.

- Answer *all* the questions.

- You have 45 minutes.

---

1. (5 marks) Determine the 8-point DFT of the real-valued sequence $x[n] = \delta[n-3]$. Plot the magnitude and phase of your answer on separate axes, ensuring that the phase lies between $-\pi$ and π.

2. (5 marks) Consider the system below

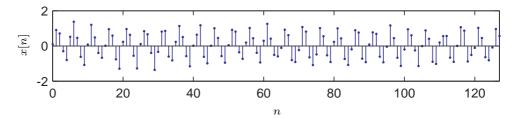

where $T = 0.001$s and

$$H(e^{j\omega}) = \begin{cases} 1 & |\omega| \leq 0.5\pi \\ 0 & \text{otherwise} \end{cases}$$

for $-\pi \leq \omega \leq \pi$. Find the output $y[n]$ if the input is $x(t) = \cos(400\pi t) + \cos(600\pi t)$.

3. (5 marks) Find $w[n] = x[n] * y[n]$ with

$$x[n] = e^{j\pi n/3} \quad \text{and} \quad y[n] = \frac{\sin(\pi(n-5)/2)}{\pi(n-5)}.$$
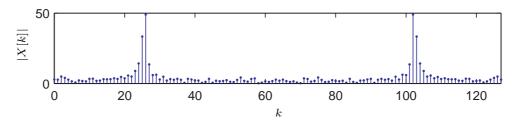

4. (5 marks) Two students want to analyse a signal from a microphone. They digitise a
sample of 128 points, obtaining the signal below:

They decide to investigate the apparent periodicity by looking at the signal in the
frequency domain. To do this they calculate the DFT

$$X[k] = \sum_{n=0}^{127} x[n] e^{-j\frac{2\pi}{128}kn}$$

for $k = 0, \ldots, 127$, which has the following magnitude plot:

(a) What is the dominant frequency present in the signal, measured in radians per sample?

(b) The quantity $|X[k]|$ as calculated is a poor estimate of the spectrum of the microphone
signal. Why is this so? What can be done to improve the estimate?
